

## Introduction to the study of Mechanical Oscillations

1. Make a Simple Pendulum as shown below.

One oscillation is, for example, from A to B and back to A. In a) to d) below,  $r$  is the initial *amplitude* of the oscillation; this means the initial displacement of the “bob” from its equilibrium position.

Find the time period (the time for one oscillation) of the pendulum under the following conditions

- a)  $l = 30\text{cm}$      $m = 20\text{g}$      $r = (\text{about}) 2\text{cm}$
- b)  $l = 30\text{cm}$      $m = 20\text{g}$      $r = (\text{about}) 4\text{cm}$
- c)  $l = 30\text{cm}$      $m = 50\text{g}$     (call this result  $T_1$ )
- d)  $l = 60\text{cm}$     (call this result  $T_2$ )

Calculate the ratio  $T_2/T_1$ .

How does the time period depend on i)  $l$  ii)  $m$  iii)  $r$  ?

2. Measure the time period of a Mass/Spring Oscillator as shown below.

Try with masses of  $m$  and  $2m$  and initial amplitudes of about 0.5 and 1cm.

Try first with a “weak” spring then with a stronger spring. How does the time period depend on i)  $m$  ii)  $r$  iii) the strength of the spring ?
